Rigid Body in Equilibrium : Edexcel Mechanics M2 January 2011 Q7 : ExamSolutions

A rigid body is a system of many particles. It is not essential that each of the particles of a rigid body behaves in a similar manner like the other particle. Depending on the type of motion every particle behaves in a specific way. This is where the equilibrium of rigid bodies comes into play. Let's find out more.

Home → Equilibrium of a Rigid Body When some external forces (which may be concurrent or parallel) are acting on a stationary body, the body may start moving or may start rotating about any point. But if the body does not start moving and also does not start rotating about any point, then the body** is said to be in equilibrium. 1.12.1.

Rigid Body Equilibrium

A rigid body is in equilibrium when it is not undergoing a change in rotational or translational motion. This equilibrium requires that two conditions must be met. The first condition is related to the translational motion. The vector sum of the forces on the body must be zero:

Equilibrium of Rigid Bodies • Definition: Equilibrium is the state when all the external forces acting on a rigid body form a system of forces equivalent to zero. There will be no rotation or translation. The forces are referred to as balanced.

Equilibrium of Rigid Bodies

equilibrium: The state of a body at rest or in uniform motion, the resultant of all forces on which is zero. A child's seesaw, shown in, is an example of static equilibrium. An object in static equilibrium is one that has no acceleration in any direction. While there might be motion, such motion is constant.
